

REMARKS

This amendment is responsive to the Final Office Action dated August 21, 2009.

Applicant has amended claims 1, 6, 8, 11, 18, 27, 32, 39-41 and cancelled claims 5, 7, 9-10, 14, 16, 23-25, 31, 34, 35, 37 and 38. Claims 2-4, 17, 28-29, and 36 were previously cancelled. Claims 1, 6, 8, 11-13, 15, 18-22, 26, 27, 30, 32, 33 and 39-41 are pending upon entry of this amendment.

Amendments

Applicant has amended claim 1 to include elements previously presented in dependent claim 5.

Applicant has amended claim 8 to include elements previously presented in dependent claims 9 and 10.

Applicant has amended claim 11 to include elements previously presented in dependent claim 14.

Applicant has amended claim 18 to include elements previously presented in dependent claims 23-25.

Applicant has amended claim 27 to include elements previously presented in dependent claim 31.

This Amendment raises no new issues and require no new search. Furthermore, the amendments present the claims in a better form for appeal. Consequently, the Amendment should be entered.

Claim Rejection Under 35 U.S.C. § 103

In the Final Office Action, the Examiner rejected claims 1, 5, 8-16, 18-27, 30-35 and 37-41 under 35 U.S.C. 103(a) as being unpatentable over Sankaran (US 2003/0231587) in view of “BGP Restart Session After Max-Prefix Limit,” Cisco Systems and “TCP/IP Network Administration,” Hunt. The Examiner rejected claim 7 under 35 U.S.C. 103(a) as being unpatentable over Sankaran in view of TCP/IP Network Administration, Hunt. The Examiner rejected claim 6 under 35 U.S.C. 103(a) as applied to claims 1 above, and further in view of Rochberger et al. (US 6,212,188). Applicant respectfully traverses the rejection. The applied references fail to disclose or suggest the inventions defined by Applicant’s claims, and provide no teaching that would have suggested the desirability of modification to arrive at the claimed invention.

Cisco Systems

As a preliminary matter, Applicant submits that all of the rejections based on Cisco Systems are improper as the evidence does not establish the reference as prior art. Specifically, on form PTO-892 the Examiner cites Cisco Systems as having a date of “2003.” The Examiner fails to attribute any month or day to the publication. The present application has a filing date of October 17, 2003. Consequently, the Examiner has failed to establish that Cisco Systems predates the present application and, therefore, has failed to establish that Cisco System qualifies as prior art against the present application. Moreover, the Cisco Systems reference has a 2003 copyright date on pg. 1 but also includes a 2005 copyright date on pg. 21. Consequently, the evidence set forth by the Examiner has not established which portions of Cisco Systems were even published in 2003. The rejection is improper and should be withdrawn.

Claims 1, 5, 8–16, 18–27, 30–35 and 37–41

Applicant has amended claim 1 to include elements previously presented in dependent claim 5. Claim 1 requires maintaining a count of routes exported from an exterior routing protocol executing on a network device to an interior routing protocol executing on the network device and rejecting additional routes exported from the exterior routing protocol executing on the network device to the interior routing protocol executing on the network device when the count exceeds an export limit. Amended claim 1 also requires updating routing information to associate the routes with a maximum metric that defines a maximum distance from the network device to neighboring network devices when the count exceeds the export limit, and advertising the updated routing information to a network device, as previously presented in claim 5.

Before addressing the cite prior art, Applicant points the Examiner to paragraphs [0037] and [0038] of the present application to aid the Examiner’s understanding of the claim language by way of example. These paragraphs describe how, upon entering an overload condition when the prefix count exceeds the prefix limit, one embodiment of the exemplary router modifies its routing information to set routes to a maximum metric so as to effectively direct the other routers of the network not to use it when forwarding network traffic and effectively remove the router from the network. In this way, the router avoids network failure. These paragraphs state:

[0037] If the prefix count exceeds the prefix limit, customer router 10A automatically enters an “overload” condition. While operating in the overload

condition, customer router 10A assumes all routes learned from an exterior protocol are invalid and clears them from its routing information, e.g., routing tables. Customer router 10A also rebuilds its interior routes, preferably to a maximum metric, e.g., the maximum effective “distance” between it and neighboring routers in the network. Customer router 10A advertises the updated routing information with the maximum metric to other peer interior routers, e.g., customer routers 10B and 10C.

[0038] In this manner, customer router 10A effectively directs the other interior customer routers 10B and 10C to find other routes through the network, effectively removing customer router 10A from the network and avoiding network failure.

With respect to the elements previously presented in claim 5, the Office Action cited Sankaran at ¶¶ 3, 5. In general, Sankaran discloses rejecting routes by a router “based upon the volume of routes in the router.” Sankaran, ¶ [0009]. That is, Sankaran discloses establishing thresholds for discarding routes based upon a volume of available storage space of a router. *See, e.g.,* Sankaran, ¶ [0035]. The cited portions of Sankaran describe conventional routing protocols (BGP, ISIS) and the fact that some networks may have redundant routes. The techniques by which the Sankaran router discards routes from its own route table fails to teach or suggest a router advertising routing information that has been rebuilt and modified in a certain way so as to instruct other routers to temporarily avoid using the router. The cited prior art fails to teach or suggest updating routing information *to associate the routes with a maximum metric that defines a maximum distance from the network device to neighboring network devices* when the count exceeds the export limit; and advertising the updated routing information to a network device, as required by claim 1.

Further, Applicant has amended independent claim 8 to include elements previously presented in dependent claims 9-10. As amended, claim 8 recites receiving a prefix limit command that specifies an export limit and an associated one of a plurality of instances of an interior routing protocol executing on a network device, and maintaining respective counts of routes exported from an exterior routing protocol executing on the network device to each of the instances of the interior routing protocol executing on the network device. Claim 8 further requires identifying one of the instances of the interior routing protocol to which the routes were exported, comparing the respective count for the identified one of the instances to the prefix limit specified by the command for the identified instance, and rejecting additional routes exported to

the identified one of the instances of the interior routing protocol based on the comparison when the count exceeds the export limit for the instance.

Before addressing the prior art, Applicant points the Examiner to paragraphs [0044] and [0045] of the present application to aid the Examiner's understanding of the claim language by way of example. These paragraphs describe how one embodiment of the present invention provides a command syntax by which a remote client can submit commands to direct a router to apply different prefix limits to different "instances" of a given interior routing protocol executing on that router:

[0044] In accordance with the principles of the invention, remote client 46 may interact with management interface 47 to configure router 10A to operate in accordance with the presently described prefix limit mode. Specifically, management interface 47 supports a command syntax in which a prefix limit command is used to direct router 10A to operate in prefix limit mode. The command syntax allows remote client 46 to specify a maximum number of routes that customer router 10A may export from an exterior protocol, e.g., BGP 32A, to a particular interior routing protocol, e.g., OSPF 32B or ISIS 32N. In addition, the command syntax allows remote client 46 to apply different prefix limits to different "instances" of a given interior routing protocol. For example, remote client 46 may specify a different prefix limit for different level of ISIS protocol 32N of ISIS or different instances of OSPF.

[0045] The following illustrates an exemplary syntax for the prefix limit command.

```
set routing instances instance_A {  
    set protocols {  
        [protocol name] {  
            prefix-export-limit [N]  
        }  
    }  
}
```

In the above-illustrated command syntax, the set protocols command directs management interface 46 to apply the configuration data to the protocol 32 specified by the protocol name parameter. In addition, the instance parameter may be used to

identify a particular instance of the specified one of protocol 32. The prefix-export-limit command, referred to generally herein as the “prefix limit” command, directs management interface 47 to set a prefix limit N for the specified protocol instance.

With respect to the elements previously presented in claims 9-10, the Examiner cited Sankaran at ¶¶ 43-45 and Cisco pg. 4, step 4 and stated that Cisco teaches “a maximum prefix limit to a neighbor is defined.” As set forth above, the Examiner has not established that Cisco qualifies as prior art and for this reason alone the rejection is improper. Further, Cisco does not refer to limits on routes exported between routing protocols on the same router, as recited by the claim. Instead, Cisco describes a configuration parameter that limits the number of routes one router can receive from another router for a give routing protocol, i.e., BGP, over a communication session between the routers. This has nothing to do with a router being able to set different prefix limits for different instances for the same interior routing protocol executing on the same router, e.g., different instances of OSPF or different instances of ISIS executing on the same router. The Examiner is perhaps confusing communication sessions between routers (which may all relate to the same BGP routing instance) with different instances of the same routing protocol on a router. Consequently, the rejection is improver for at least these additional reasons.

Independent claim 11 recites a method comprising receiving at a network device an export limit command from a client, and counting, in response to the export limit command, a number of routes exported from an exterior routing protocol process executing on the network device to an interior routing protocol process executing on the network device. Amended claim 11 further recites, when the number of routes exported from the exterior routing protocol process to the interior routing protocol process exceeds an export limit, operating the network device in an overload condition in which the network device: (i) updates routing information of the interior routing protocol to clear the routes previously exported from the exterior routing protocol, (ii) rebuilds the routing information of the interior routing protocol by updating the routing information of the interior routing protocol to associate interior routes with a maximum metric that defines a maximum distance from the network device to neighboring network devices, and (iii) advertises the updated routing information to another network device. For reasons set forth above with respect to claim 1, the cited references do not teach or suggest rebuilding routing information in the manner recited by claim 11 *to associate interior routes with a maximum metric that defines a maximum distance from the network device to neighboring network devices.*

Moreover, for reasons set forth above, the reference fail to teach or suggest rebuilding the routing information in the specific manner when the network device is operating in an overload condition because the number of routes exported from an exterior routing protocol on that network to an interior routing protocol exceeds an export limit.

The cited references fail to teach or suggest the element of independent claims 18, 27 and 33 for reasons similar to those set forth above.

For at least these reasons, the Examiner has failed to establish a *prima facie* case for non-patentability of Applicant's claims under 35 U.S.C. 103(a). Withdrawal of this rejection is requested.

CONCLUSION

All claims in this application are in condition for allowance. Applicant respectfully requests reconsideration and prompt allowance of all pending claims. Please charge any additional fees or credit any overpayment to deposit account number 50-1778. The Examiner is invited to telephone the below-signed attorney to discuss this application.
